

NASA TECH BRIEF

NASA Tech Briefs are issued by the Technology Utilization Division to summarize specific technical innovations derived from the space program. Copies are available to the public from the Clearinghouse for Federal Scientific and Technical Information, Springfield, Virginia, 22151.

New Alloy Brazes Titanium to Stainless Steel

The problem: Brazing titanium to stainless steel without embrittling the metals at the brazed interfaces. The fusion point of the brazing alloy must not exceed 1685°F, since titanium becomes undesirably brittle above this temperature (beta transition temperature of pure titanium). Although there are a number of alloys that can be used for brazing titanium below the beta transition temperature, they do not meet all of the following additional NASA requirements: (1) The brazing alloy must be inert to nitric acid; (2) it must form a high-strength bond; (3) under vacuum test, helium leakage through the sealed joint must not exceed approximately 0.63 cc per year; (4) the alloy must metallurgically bond to titanium and stainless steel without the formation of undesirable compounds at the interfaces.

The solution: A brazing alloy having the following composition in percent by weight: 81.1 palladium, 14.3 silver, 4.6 silicon.

Tests performed with samples of this alloy have yielded the following results: (1) The homogeneous solid is inert to nitric acid; (2) the sealed joint meets specifications for operation under high vacuum; (3)

the ultimate tensile strength of the joint is approximately 75,000 psi; (4) the alloy forms a metallurgical bond, with alloy interfacial penetration of 0.0015 inch into titanium and 0.003 inch into stainless steel; (5) it has excellent flow characteristics at a brazing temperature in the range of 1395°F to 1450°F.
